**Nursing Intervention at Home Care to Prevent Recurrence of Cardiac Stent**

Faten Khayrat, Omaima Mohamed Esmat, Zainab Awad Mohamed
Community Nursing Department, Faculty of Nursing - Ain Shams University.

**Abstract**

**Background:** Home health care services were to help individuals to improve function and live with greater independence, to promote the client’s optimal level of well-being, to assist the patient to remain at home avoiding hospitalization or admission to long-term care. Stents reduce angina (chest pain) and have been shown to improve survivability and decrease adverse events in an acute myocardial infarction. The **Aim** of the study is to measure the effect of a nursing intervention at home to prevent recurrence of cardiac stent. **Research design:** A quasi experimental design was utilized. **Settings:** The study was conducted at outpatient clinics of cardiovascular surgery hospital of Ain Shams University hospitals. **Subjects:** A purposive randomly selected sample which composed of one hundred and thirty four clients after cardiac stent. **Tools** of data collection: First: Structured interviewing questionnaire, it was composed of 3 parts, part one: socio-demographic data, part two: Assess client’s knowledge regarding cardiac stent. Part three: client practice related to behavioral habits, nutrition and physical activities. Second tool: Environmental assessment for home condition (ventilation, cleanliness’). Third tool: Client medical record to assess client diagnosis, investigations, and treatments vital signs, and weight and height **Results:** Revealed a highly statistical significant relation between clients practice and knowledge of clients regarding cardiac stent pre & post nursing intervention. **Conclusion:** This study concluded that, the nursing intervention program had a highly statistical significant relationship with improved knowledge and practices of clients of cardiac stent and change life style to prevent recurrence of cardiac stent. **Recommendations:** Building up a national strategy for home care for enhancement knowledge and help in change life style for clients with cardiac stent to prevent recurrence cardiac stent. Expansion of health insurance services at home to covers the needs of cardiac stent clients by nursing.

**Key words:** Nursing intervention, Cardiac stent, and Home care nurse.

**Introduction**

CVDs (cardiovascular diseases) are the number 1 cause of death globally: more people die annually from CVDs than from any other cause. An estimated 17.5 million people died from CVDs in 2012, representing 31% of all global deaths. Of these deaths, an estimated 7.4 million were due to coronary heart disease and 6.7 million were due to stroke. Over three quarters of CVD deaths take place in low- and middle-
income countries. Out of the 16 million deaths under the age of 70 due to non communicable diseases, 82% are in low and middle income countries and 37% are caused by CVDs (World Health Organization, 2014).

Home care is supportive care provided at home. Care may be provided by licensed professionals who provide medical treatment needs or by professional caregivers who provide daily assistance to ensure the activities of daily living (ADLs) are met. In-home medical care is often and more accurately referred to as "home health care" or formal care. For terminally ill patients, home care may include hospice care. For patients recovering from surgery or illness, home care may include rehabilitative therapies (Christensen, & Grönvall. 2011).

Community health nurse have an ideal opportunity to enhance health promotion activities that can reduce the risk of coronary artery disease as educators and role models for their families, communities and patient. For effective prevention and treatment, it is important that nurse consider the psychological parameter that may affect health behaviors community health nurse can promote healthy lifestyle patterns that reduce the risks of recurrence cardiac stent for example physical activity, regular meals and nutrition and weight counseling are all areas where nurse may help to reduce the risk factors (Miller et al., 2010).

Role of Community Health Nurse Toward Patient with Cardiac Stent: assessment of patient’s needs, modification of patients behavior towards more self-control, activate participation in decision making, development of self –care to handle the heart disease and possible complication, assessment of possible risk factors, implement of realistic goals, support to adopt appositive attitude towards the disease and alleviate psychological distress (Polikandrioti & Notkou, 2011).

Lifestyle changes in the form of increased physical activity, dietary modification/weight loss, and smoking cessation are of proven benefit and may improve outcomes in as quickly as six months. Drug therapies these therapies work, in part, by ameliorating the risk attributable to the major modifiable risk factors of hypertension, dyslipidemia, diabetes, and smoking. Most clinicians prefer to recommend life style modifications prior to the initiation of drug therapy (Eckel et al., 2013).

Coronary heart disease is linked to various lifestyle factors such as diet, physical activities, smoking and stress. Life-style changes are an important activity, smoking and stress. Life-style changes are an important part of any treatment for angina. Some changes may be useful in reducing the frequency of attacks by identifying and modifying the activities and situations that precipitate these attacks. Anand et al (2008).

Regular physical activity is an important part of healthy heart program, because physical activity both directly reduces heart disease risk and reduces chances of developing other risk factors for heart disease. Regular physical activity reduce LDL (bad) cholesterol, increase HDL (good) cholesterol and lower high blood pressure and control diabetes. Physical activity can help to lose excess weight or stay at desirable weight which also help to lower risk of CAD (Heliberg, 2008).

The professional nurse to be in the front line of cardiac rehabilitation team the main goal of cardiac rehabilitation is to prompt patients participate in their therapeutic treatment regimen to such an extent that they can achieve living almost a
normal life .cardiac rehabilitation programs 
comprising prescriptive exercise ,health 
education and counseling ,yield compelling 
improvements in cardiac morbidity and 
mortality of participants (Beckie & 
Beckstead, 2010).

Significance of the study

In Egypt: the distributors of 
intervention tools for the years 2010 to 
2015. Analysis of these data showed a 
steady growth of primary PCI (percutaneous 
coronary intervention) amounting to a 
threefold increase over the six-year period. 
There are increasing numbers of PCI- 
capable canters, especially in Cairo. Almost 
55,000 PCIs are performed yearly in Egypt 
utilizing around 100,000 stents; the 
percentage of drug-eluting stents (DES) 
used has increased to 65-70% (90% in 
private and insured patients). Ahmed 

According to latest WHO data 
published in coronary heart disease in Egypt 
reached 78,897 or 21, 37% of total 
population deaths. The leading global risks 
for mortality in the world are high blood 
pressure, tobacco use and overweight and 
obesity. These risks are responsible for 
raising the risk of chronic disease such as 
heart disease, diabetes mellitus and cancer 
(WHO, 2011).

Aim of the study

The aim of this study was to measure 
the effect of nursing intervention for patient 
with cardiac stent through:

1- Assessing client knowledge and 
practice related to lifestyle home 
according to patient needs after stent.

2- Implementing nursing intervention at 
home care to prevent recurrence of 
cardiac stent.

3- Evaluating the outcome of nursing 
intervention at home cares to prevent 
recurrence of cardiac stent.

Research hypothesis:

- The nursing intervention at home care will 
prevent recurrence of cardiac stents.

- The nursing intervention improve lifestyle 
(smoking, nutrition, exercise, stress 
and sleeping)?

Subjects &Methods:

Study design:

A quasi experimental design used to 
determine the effect of nursing intervention 
program on lifestyle of clients with cardiac 
stent.

Research Design

The study included four designs:

I. Technical Design .

The technical design included the 
research design, settings, subjects and tools 
used in the study.

Setting:

This study was conducted at the 
following setting, Ain Shams University 
Hospital outpatient clinic of cardiovascular 
surgery hospital.

Sampling:

A purposive randomly selected sample 
was used in the study. All cardiac stent 
attending the selected setting for follow up and 
treatment after cardiac clients with stent within 
six months until sample size was 
achieved.both male and female their age (40-
60)years as well as free from (diabetes 
mellitus) 
clients (134) have been selected for the 
study regardless of their age, educational level, 
and occupation, but all are attending to 
outpatient clinic after cardiac stent...
Nursing Intervention at Home Care to Prevent Recurrence of Cardiac Stent

Tools of data collection:

Three tools were used to collect the data.

First tool: Structured interviewing questionnaire for clients with cardiac stent

It was developed by the researcher based on reviewing the current relevant literature. It was written in simple Arabic language to suit client’s level of understanding.

This tool was validated by the expertise from faculty of Nursing. It included the following:

A) Biosociodemographic data: age, sex, level of education, occupation, place of residence, marital status.

B) Client knowledge about cardiac stent, complication after stent, medication used after stent. through Pre-Post program: Questions Prepared by the researcher based on literature concerning with client knowledge about cardiac stent related to the meaning of stent, types, risk factors, treatment and complications.

➤ Scoring system:

Answers were grouped into correct =1, while incorrect = 0 based on literature. Total clients knowledge was classified into the following scale good knowledge 1 while poor knowledge scored 0.

C) Client practice related to behavioral habits, nutrition and physical activities through: (pre/post program).

Assess client’s practice through asking questions regarding life style activities after cardiac stent

➤ Scoring system:

Cardiac stent clients reported practices were evaluated based on recent literature, their responses were divided into.

Correct =1, while incorrect = 0.

Third Tool: Medical records will be checked to collect data about client diagnosis and history background, vital signs, weight, height.

➤ Scoring System:

Scoring system: According to the measure of the clients from the medical file normal =1, abnormal = 0.

Content validity:

This tool was tested through five expertise’s from the staff of Faculty of Nursing, Community Health Nursing Department, and Ain Shams University.

Administrative and Ethical Design:

An official permission was granted by submission of formal letter issued from the administrators of Faculty of Nursing Ain Shams University to administrators of cardiovascular and surgery hospital after explanation of purpose of the study and handing out copies of protocol in order to obtain official permissions of cooperation.

Ethical considerations:

Oral Consents from clients with cardiac stent were obtained to ensure their willingness to engage in the study after explaining its purpose and nature. The investigator also provided strict concern to keep their privacy. Reassuring that study would never expose them to any harm, as information was kept confidential and they could withdraw from the study at any time.

Operational Design

A. Pilot Study:

A pilot study was carried out on 10% from 134 clients who were excluded later in the study sample. The aim of the pilot study was to test clarity, simplicity and applicability of
the study tools. Necessary modifications were carried out.

**B-Field work:**

- Informed consent was secured before collecting data.
- All clients were interviewed at outpatient clinics’ halls and working areas, after explanation of study aim and objectives.
- Actual field work was carried out in the period from August 2015 to end of January 2016.
- The assessment phase (pre-test) was done for 134 clients and post-test was carried out 6 months after program implementation.
- Teaching sessions were conducted at meeting halls and working areas of outpatient clinics.
- The average time consumed to fill tools was 30 minutes.

**Statistical design:**

Data were revised, coded, analyzed and tabulated using the number and percentage distribution and processed through computer SPSS version 21 was used for analysis of data.

The following statistical techniques were used:

- Percentages, mean value, standard deviation, chi-square (X²), probation probability (p-value), T test.

**Significance of results:**

When P is < 0.05, it is statistically significant difference.

When P is < 0.01 or P< 0.001 it is high significant difference.

**Result**

**Table (1):** Shows that that 70.1% of clients were male the mean age of clients 53.2±0 regarding education level 17.2% of cardiac stent clients were illiterate, as regard occupation, 59.7% working in relation to marital status 87.3% were married in relation to working hours 50% of cardiac stent clients working 6 hours daily.

**Table (2):** reveals that water and caffeine consumption/day 70.95% & 8.2% of clients were drinking black tea and coffee daily in pre program compared to 30% & 2.9% post program.

**Table (3):** shows that health problem of the client pre & post nursing intervention program (cough, constipation, hyperacidity, chest pain and two approaches) statistical significance (p<0.001).

**Table (4):** shows that highly statistical significance differences between pre/post interventional program in relation to cholesterol and low-density lipoprotein measurement (p<0.001).

equivalent as their highest education level. This result disagreement with the study.

Discussion

The present study showed that the study sample mean age ranged between (53.2±7.0 years). Regarding to gender more than two third of the study sample was male and one third was female. This finding was consistent with the result of Mary, (2016). The aim of this study was to investigate participants’ risk factor profile, knowledge of coronary heart disease, and the influence of demographic and risk factors on this knowledge in Dublin, Ireland. This study found that Seventy-six percent were male and this result in disagreement with the study done in Tabriz university of medical science in Iran to assess socio-demographic status and coronary heart disease by Steptoe & Kivimaki (2012) who found that the mean age was forty four (range 17-70) years more than half of the participants were women.

Regarding educational level among study sample the results revealed that less than half of the sample were secondary school less than one quarter were illiterate and also less than one quarter were university level. This finding was consistent with the result of (Mary, 2016) on study assess Cardiovascular Health Status by Occupational Group study nearly half of the study sample reported secondary school or done in Finland to assess difference between coronary artery disease patients educational groups which conducted by Pekkanen et al. (2008) reported that almost three quarter were illiterate, one quarter possessed no academic qualification and just five percent were on the college graduate level.

Regarding occupation, the present study revealed that more than half of the cardiac stent clients were employees. This result agreement with Taylor et al. (2014) who assessed in United State Cardiovascular Health Status by Occupational Group accounting for about more than half of all U.S. adults, the working population is an important demographic group to evaluate with regard to cardiovascular health status. Regarding working hours, the present study revealed that half of the working clients were working 6 hours daily this results agreement with Sadie et al. (2016) in the study to examine the presence of a dose–response relationship between work hours and incident cardiovascular disease, which showed that half of the participants working 36 hours in the week?

Regarding marital status, the finding of the present study showed that more than two third of clients were married and less
Nursing Intervention at Home Care to Prevent Recurrence of Cardiac Stent

than one third were widowed. This result agreement with the study by Machenbach et al., (2008) to assess Biosocioeconomic inequalities in health in 22 European countries reported that eight percent of these interviewed reported their marital status as married and one fifth were widowed.

In relation to residential area the present study showed that the majority of the clients were from urban area while few of them from rural area. This result agreement with the study done in North England to socioeconomic status and cardiovascular disease by Clark et al., (2009) that among the majority of participants the place of life were urban and few of participants were in rural locations.

Regarding to smoking sessions, two third of clients with cardiac stent was active smoker in preprogram, less than half of smoking clients quiet smoking in post program. This result agreement with study by Mary et al., (2016) on risk factors among post percutaneous coronary intervention patients which showed that smoking remained high less than half among study group; smoking rates among post-PCI patients and cardiac patients generally ranged from eight to fifteen percent. Also this result agreement with study by Doll et al., (2009) on mortality in relation to smoking: 50 years observations on male British doctors indicating that for cardiac patients, it was also very important to stop smoking. A study showed that if one third of cardiac patients stop cigarette smoking, it resulted in a thirteen percent reduction in cardiovascular mortality.

The present study showed that more than two third of the study group was smoking and one third suffered from passive smoking in preprogram compare with less than half of them in postprogram. This result coincide with study by Bonita, (2009) in New Zealand on passive smoking as well as active smoking increase the risk of acute stroke, showed that passive smoking significantly increased the risk of stroke and high blood pressure in men and women.

In current study, client’s who quitted smoking due to the risk of recurrent cardiac stent and chest pain and after the program & followed up and booklet contain method to quitting smoking gradually.

According to physical exercise practicing the present study showed that more than two third from clients under study were practicing physical exercise in post program with highly statistical significance between pre & post program. This result agreement with study by Stephanie et al., (2016) study lifestyle changed after cardiac revascularization which showed that half of study group have exercises practice. Also this result agreements with study published by Blaire et al., (2009) in American journal for cardiology the study reported a significant beneficial effect of an exercise program. Also Schnohr et al., (2010) reported that mortality risk reduction for an increased level of physical activity was obtained from a meta analysis on the effect of exercise-based revalidation.

Regarding too fat in diet the present study showed that more than half of study sample were using fat in diet in preprogram mean while less than quarter in post program.

This result agreement with study conducted by Kimiagar et al., (2009) in Iran on food consumption revealed that the contribution of saturated fatty acids to dietary energy exceeded the recommendation limits.

The same, Brunner et al., (2007). Indicated that changes in dietary pattern lead to impressive changes of the health status. there was a decrease of
thirteen serum cholesterol when people changed from the consumption of butter to vegetable oil margarine from whole –fat milk to low-fat milk and from boiled to filtered coffee. Besides, there was a decrease in blood pressure as a result of sodium intake reduction and an increase in fruit and vegetables consumption, which thus contribution to more than half declined in coronary heart disease mortality in men and two third declined in women.

On the light of the previous result the nutritional pattern of cardiovascular disease improved after implementation nursing intervention program due to acquired knowledge and healthy nutritional practices that helped in modifying their nutritional pattern.

In relation to caffeine consumption /day the present study showed that about half of the clients under the study drank tea in preprogram compared with one quarter of the study sample post program.

David Kiefer, (2017) Drinking large amounts of black tea, or more than four or five cups a day, might cause health problems. That was mostly because of caffeine-related side effects.

Side effects of black tea (most often in high amounts) might include: Anxiety and difficulty sleeping, faster breathing, headache, increased urination, irregular heartbeat, nausea and vomiting, nervousness and restlessness, ringing in the ears, tremors. Black tea or black tea supplements might interfere with other medicines and supplements are taking. Some medicines could cause caffeine to stay in body longer than usual.

American Heart association (2014) managing stress was a good idea for overall health and researches were currently studying whether managing stress was effective for heart disease. A few studies had examined how well treatment or therapies worked in reducing the effects of stress on cardiovascular disease. Studies using psychosocial therapies involving both psychological and social aspects were promising in the prevention of second heart attacks.

This result was attributed to acquired knowledge and methods for stress management through educational booklet and demonstration.

In relation to sleep hours /day the present study showed that two third of clients were sleeping less than six hours /day and decreased to half post program.

This finding of this study was in agreement with WenruWangetal., (2016) who followed the study group at home and found that more than two third of clients was sleeping hours less than six hours. Also Redline et al., (2010) who reported that poor sleep has been linked with high blood pressure, atherosclerosis, heart failure, heart attack and stroke, diabetes and obesity also.

This finding of this study agreement with Redline et al., (2010) who told that poor sleep had been linked with high blood pressure, atherosclerosis, heart failure, heart attack and stroke, diabetes and obesity. Also Leinum et al., (2009) added that poor sleep increase level of C-reactive protein and other substances that reflected active inflammation. It also reviewed up the body sympathetic nervous system which is activated by fright or stress.

This result was attributed to chest pain (angina) and difficult in sleeping that disturbed sleeping.

In relation to obesity lead to heart disease showed that quarter of the client agreement with that compared to more than two third after program.
Nursing Intervention at Home Care to Prevent Recurrence of Cardiac Stent

In relation to total knowledge score among study sample the present study showed that two third of clients had correct knowledge about obesity after program implementation.

This result went in the same way with result conducted by Olga Kadda, et al., (2012) Nursing education in cardiac rehabilitation could improve health outcomes and reduced the risk of a new cardiac event. A health educational program organized by nurses for patients after a cardiac event or surgery improves patients’ knowledge of their illness and awareness of behavioral changes to prevent a new event or readmission to hospital.

This result was attributed to acquisition more knowledge during implementation the program both from educational booklet & open discussion.

According to the research hypothesis: implementation a nursing intervention program at home for clients with cardiac stent would improve their knowledge, attitude and practices.

In relation to total knowledge score among study sample the present study showed that more than half of clients had correct knowledge about cardiac stent post program.

Conclusion

On the light of the results and answers on research hypothesis the study was concluded that:

highly significant correlation between clients’ knowledge and practice after implementation of the nursing intervention program, also there was highly statistical significant relations between clients age, education and occupation with their knowledge and practices regarding cardiac stent. It also showed a highly significant correlation between clients practice and knowledge after implementing the nursing intervention program.

Recommendation:

The findings of this study suggested the following recommendations:

1- Building up a national strategy for home care for enhancement knowledge and help in change life style for cardiac stent clients to prevent recurrence of cardiac stent.

2- Continuity of nursing intervention to raise the health awareness and knowledge of family about risk factors for cardiac stent and encourage them to adopt a healthy dieter behavior, promote physical exercise and smoking session.

3- Raising community awareness through educational campaigns by home care nurse to prevent recurrence of cardiac stent.

4- Providing cardiac outpatient clinics in governmental hospital with rehabilitation centers to follow up lifestyle promoting for cardiac stent clients.

Financial Support

No funding was received.

Conflict of interest:

No Yes
